

**Case of unerupted teeth (primary failure of eruption) treated with
TUBERCULINUM**

Presented here are two cases of unerupted permanent incisors in two different children aged 6 and 7 years, one male child and one female child respectively.

The medicine given was Tuberculinum 200 one dose to both of them when they presented with above mentioned complaint. The first child had not erupted the tooth for six months had started signs of eruption within 10 days, which rapidly developed and completed eruption by next visit after a month. The second child had not erupted the upper incisor for 4 months, started showing signs of eruption after 15 days of the medicine.

Explanation

Generally, calp hos 6x comes to mind for such kids and many parents come seeking the same. However, the primary failure of eruption is a deeper miasmatic condition (most of the times) than just deficiency of calcium metabolism. Tuberculinum covers this condition and strikes it at the root or clears up the case, paving way for the next remedy if nothing else.
